Thus, it can be stated that current turbulence models are restricted to various zones of application. Turbulence models can also be classified as either eddy-viscosity or stress-transport models 6. Eddy-viscosity models rely on the Boussinesq 8 concept, which models the turbulent shear stress as the product of an effective viscosity and a mean rate of strain. The effective viscosity is proportional to the velocity and length scales of the turbulence in the various regions of the flow. Eddy-viscosity models can be further classified according to the method of determining the effective viscosity; in other words, the various eddy-viscosity models are functions of the method used to describe the velocity and length scales of turbulence. They are classified as either zero-, one-, or two-equation models, where the designation refers to number of field equations used in addition to the usual mean flow equations. The simplest is, of course, the zero-equation model, which determines the eddy viscosity based entirely on the properties of the mean flow. The two primary examples of this type are those of Cebeci and Smith 9 and Baldwin and Lomax 10. These models are widely used in practical engineering applications for simple shear flows and in many Navier-Stokes codes 5. The one-equation models typically rely on the solution of the turbulent kinetic energy equation to represent the velocity scale, and the two-equation models incorporate the solution of an additional equation which represents the length...
